

EC102 Macroeconomics

Professor Francesco Caselli

Revision Document

Cedric Tan

April 2019

Abstract

This is a review of macroeconomic lectures by Francesco Caselli in Lent Term of 2019. The notes are mine fully and may not be authentic to the lecturer's as they have been modified.

The format of this material is usually recounted slide by slide but some slides may be merged together as the material fits appropriately with one another.

Contents

1	Introduction to Macro	5
2	Economic Growth	6
2.1	Preliminary Questions on Growth	6
2.2	Measuring Growth	6
2.2.1	Measuring Growth: GDP per Capita	6
2.2.2	Measuring Growth: Median Income	7
2.2.3	Measuring Growth: Multi-dimensional	7
2.2.4	Measuring Growth: Depletion	7
2.2.5	Focus on Growth	7
2.3	Sustainability and Desirability of Growth	7
2.3.1	Problem 1: Running out of resources	8
2.3.2	Problem 2: Environmental Degradation	8
2.3.3	Is growth even a good thing?	8
2.4	Economic Growth: Appendix	9
2.4.1	Formulae and Definitions	9
2.4.2	Figures	9
3	Growth Engines	10
3.1	Capital Accumulation	10
3.1.1	Definitions	10
3.1.2	Accumulation and Growth	10
3.1.3	Nature of Investment	10

3.6.1	Formulae and Definitions	18

4	Economic Fluctuations	19
4.1	Demand Shocks	19
4.1.1	GDP Composition	19
4.1.2	Aggregate Demand	19
4.1.3	Narrative of the Aggregate Demand Shock	20
4.2	Counter-cyclical Policy	22
4.2.1	Fiscal Policy	22
4.2.2	Monetary Policy	24
4.2.3	Economic Activity and Policy	25
4.2.4	Unconventional Monetary Policy	26
4.3	Supply Shocks	29
4.3.1	Examples of Supply Shocks	29
4.3.2	Supply Shocks and Prices	29
4.3.3	The Relative (UN)Importance of Supply Shocks	30
4.4	Economic Fluctuations: Appendix	30
4.4.1	Formulae and Definitions	30
5	Inflation and Deflation	31
5.1	Inflation	31
5.1.1	Absolute versus Relative Prices	31
5.1.2	Inflation and Relative Prices	31
5.1.3	Inflation and Uncertainty	32
5.1.4	Benefits of Moderate Inflation	33
5.1.5	Bringing Inflation Down	33
5.1.6	Inflation Targets	33
5.2	Hyperinflation	33
5.2.1	What Causes Hyperinflation?	34
5.2.2	Ending Hyperinflation	34
5.3	Deflation	35
5.3.1	Fighting Deflation	35
5.4	Inflation and Deflation: Appendix	35
6	Unemployment	36
6.1	A Basic Model of the NRU	36
6.1.1	Labour Market Flows: Separations	36
6.1.2	Labour Market Flows: Matches	37
6.1.3	Transitions between Employment and Unemployment	37
6.2	Labour Market Policies and Institutions	38
6.2.1	Active Labour Market Policies	38
6.2.2	Unemployment Insurance (UI)	38
6.2.3	Employment Protection Legislation (EPL)	39
6.2.4	Wage Setting Process	40
6.3	Dual Labour Markets	40
6.4	Payroll Taxes	41
6.5	Unemployment: Appendix	41
6.5.1	Formulae and Definitions	41

7	The Financial System and Macro	42
7.1	Components of the Financial System	42
7.2	Balance Sheets	43
7.3	Banking Problems	43
7.3.1	Insolvency	44
7.3.2	Illiquidity	45
7.4	Financial Crises	46
7.4.1	Origins	46
7.4.2	Crisis Triggers	46
7.4.3	Crisis Catalysts	47
7.4.4	Anatomy of a Financial Crisis	48
7.5	Policy Responses	49
7.5.1	Conventional Counter-cyclical Policy	49
7.5.2	Lending of Last Resort	49
7.5.3	Nationalisations and Publicly Funded Recaps	49
7.5.4	Subsidies to Lending	49
7.6	Financial System Reform	50
7.6.1	Dealing with the Financial Sector	50
7.6.2	Stress Tests	51
7.6.3	Asset Allocation	51
7.6.4	Compensation Reform	51
7.7	Too Big To Fail (TBTF)	52
7.7.1	Dealing with TBTF 1	52
7.7.2	Dealing with TBTF 2	52
7.8	Scope of Financial Regulation	52
7.9	Financial System: Appendix	53
7.9.1	Formulae and Definitions	53
8	Brexit	53
8.1	Structure	53
8.1.1	Where Things Stood	53
8.1.2	What the Notes Address	53
8.2	Impact of Brexit	53
9	Sovereign Debt Crises	53
9.1	Causes	54
9.2	Judging Debt Sustainability	54
9.3	Currency Denomination	54
9.4	Interest Rate Spreads	55
9.5	Outcomes of SDCs	55
9.5.1	Outcome 1: Default	55
9.5.2	Outcome 2: Fiscal Adjustment and Survival	55
9.5.3	Outcome 3: Bailouts	56
9.6	SDCs and Banking Crises	56

1 Introduction to Macro

Macroeconomics is about the performance of the economy overall. Topics that will be covered in this course are as follows:

- Long-run Economic Growth
- Booms and Recessions
- Inflation and Deflation
- Unemployment
- Financial, Currency and Sovereign Debt Crises

Further to that, here are some of the big macroeconomic issues that we are facing today in (**April 2019:**)

- Why are we growing so slowly and is the slowdown permanent?
- What are the consequences of **Brexit** for UK growth?
- Has austerity been a good idea? In the UK? In the Eurozone?
- Why is inflation so low and what should Central Banks do about it?
- What will happen when Central Banks end **Quantitative Easing**?
- Will lower-income countries ever catch up to the high-income ones?
- Will there be a financial crisis in China?
- Have we done enough to prevent a new financial crisis?

Colin O'Shea: *Market sentiment always dictates what will happen. Policy implementation may not always work as it is dependent on sentiment.*

Welcome to macroeconomics

2 Economic Growth

We will begin with a definition of Economic growth:

*It is the **long run** changes in **material living standards**.*

Long run means:

- Persistent changes over time
- One generation compared to the previous
- Definitely not a quarter by quarter analysis

Material means:

- Food, housing: these are **physical objects**
- Education, healthcare
- Income to access these goods and services

2.1 Preliminary Questions on Growth

Further to this, we will ask some preliminary questions on growth to get the gears running:

- How do we measure it?
- Is indefinite growth feasible? i.e. **Growth forever on an upwards trend?**
- Is indefinite growth even desirable or **even a good idea?**

2.2 Measuring Growth

We will begin the discussion on growth by looking at various ways of measuring it

2.2.1 Measuring Growth: GDP per Capita

Definitions:

GDP: the value of all goods and services produced by an economy in a year

per Capita: divided by the total population

This indicates that everyone gets an equal share of the pie *which might not necessarily be the case hence the doubt about the measure.*

But it does provide an idea of the **standard of living within the society**

The common consumption method of measuring GDP is:

$$GDP = AD = C + I + G + (X - M)$$

2.2.2 Measuring Growth: Median Income

Definitions:

Median income: the level of income at which 50% of the population is above and 50% of the population is below.

This gives a rough indication of the income distribution within a country, something that **GDP per Capita** does not show. This can be adjusted for family size as well.

In the UK, for example:

- Median: £27,300
- Average: £27,600

2.2.3 Measuring Growth: Multi-dimensional

Further to the previous two measures of growth which are strictly numerical, we can adopt multi-dimensional measures of growth as well. These are considered holistic approaches to measurement. Examples include:

- **The Stiglitz Commission:** a dashboard approach which measures a whole host of indicators such as health, education and political voice
- **United Nations HDI:** a measure for GDP per Capita, education through literacy rates and mean years of schooling and life expectancy
- **Utility-based Index:** measures happiness through indicators such as consumption, life expectancy, inequality and leisure

2.2.4 Measuring Growth: Depletion

Another method to measuring growth is simply through depletion.

This means **we measure not what we build** but rather **what we have depleted in the process of building it**. This measure is an innovative way of seeing growth due to the economic problem of scarcity.

2.2.5 Focus on Growth

Concerning other factors such as education, life expectancy and so on, it is usually okay for us to **focus on growth** as there is a positive correlation with all the other measures:

- Over long periods of time
- Over countries with very different living standards

It simply provides a standardised measure which does not need to take in subjective accounts to be fully effective. The limitations it has can be supported by the holistic measures mentioned.

2.3 Sustainability and Desirability of Growth

Here we will discuss the sustainability of growth and whether or not an indefinite growth path is desirable in the first place.

2.3.1 Problem 1: Running out of resources

The issue is self-explanatory, when we begin to run out of natural resources, the growth trend will gradually plateau and then dip if we are unable to continue producing. Presented below are key solutions to the issue:

- **Substitution:** finding alternative solutions e.g. renewable energy rather than fossil fuels
- **Efficiency:** becoming better at using less or the equal amount for more e.g. mileage on a car has become much more efficient
- **Recycling:** reusing old unused materials again for production e.g. plastics, card etc.

Further to that, we have to recognise the role of the market and the role of public policy:

- Role of the market:
 - Spontaneity of market solutions that arise
 - Innovation from an incentive to profit
 - Creation of efficiency gains to capture a wider market share
- Role of public policy:
 - Promotion of sustainable growth
 - Use of regulation e.g. carbon caps or subsidies to promote to disincentivise or promote certain market practices.

2.3.2 Problem 2: Environmental Degradation

Environmental degradation and climate change are key issues that might affect our ability to grow. These are due to the issues cause by them that hinder economic growth such as weather patterns affecting our agriculture.

These are due mainly to externalities which:

- Arise when agents engage in activities which have an **impact on others** but has **no market** as the price adjustment mechanism is non-existent
- Have an effect on a third party during the **consumption or production** of a good or service

The technical solutions mentioned above are still key to resolving these issues but:

- Externalities are only easier to control at a local and national level
- Global externalities, which cause the most issues, is where the difficulty lies as **coordination across governments** is required but not guaranteed. *Trump and pulling the USA out of the Paris agreement is a good example.*

2.3.3 Is growth even a good thing?

Here is a proposal: **Zero Growth in rich countries.** This will allow us to:

- Have more leisure as there is no need to work

- Focus on what matters such as relationships, relaxation and pursuit of alternative activities such as your hobbies

But here are some pro-growth arguments to counter those above:

- Quantity of life is greater due to a **longer life expectancy**
- Periods of low growth lead to nasty politics: avoid this by not advocating for a **Zero Growth** policy

So perhaps we can leave the no-growth option as an individual one. You choose yourself if you want to pursue this path but it should not be one that society as a whole adopts.

2.4 Economic Growth: Appendix

Find related materials here. Some may be repeated from other appendices.

2.4.1 Formulae and Definitions

- **Growth Rate:**
 - Change is the new level divided by the initial level.
 - **Formula:** $\frac{GDP_{T2} - GDP_{T1}}{GDP_{T1}}$

2.4.2 Figures

GDP per person in Britain

Figure 1: Britain's GDP over time

GDP per person around the World

Figure 2: Britain's GDP compared to other countries NOW

GDP per Worker/Labour Productivity

Figure 3: GDP vs Productivity

Annual growth rate of UK GDP per worker

Figure 4: Britain's GDP Growth Trend

3 Growth Engines

Here we move onto the main drivers for growth in the economy. We will use an analogy of a hunting village, whereby the hunters use arrows to catch their game, to spell out these engines specifically. The engines that we will discuss are as follows:

- More arrows per hunter: **Capital Accumulation**
- Better arrows to use: **Technological Change**
- Hunting in a pack: **Management Quality**
- More hunting training: **Human Capital Accumulation**

n.b. For this example, we will assume that $Kills/worker = GDP/capita$ and $Kills\ Total = GDP\ Total$

3.1 Capital Accumulation

More arrows per hunter in our analogy is called **capital** accumulation as we have more productive resources to utilise in our day to day production of game. This is done through the process of **investment**.

3.1.1 Definitions

Beginning with some definitions:

- **Capital:** the stock of equipment and structures at a certain point in time
- **Investment:** the addition to the stock of equipment and structures

3.1.2 Accumulation and Growth

The causal mechanism for accumulation and then growth is through how workers use capital.

Think of capital as **aids in production to effectively produce more**, like how the arrows in the hunting village help with killing more animals.

Investment leads to the accumulation of this capital as there will be growth in **capital per worker**, adding to the overall stock.

Growth in capital per worker leads to growth in **GDP per worker** as each worker is more productive.

3.1.3 Nature of Investment

The nature of investment is such that there is a sacrifice of current consumption to achieve a greater level of future consumption. Some of the workers and capital are labouring to produce new capital instead of producing goods and services for immediate use.

3.1.4 Investment in an Open Economy

We can not sacrifice consumption domestically to gain investment into the economy through the use of imports: **capital goods are imported whilst domestic workers dedicate themselves to consumption goods.**

However, this implies **debt accumulation** as you are borrowing funds to pay for these expensive imported capital goods. Since foreign debt cannot be accumulated **indefinitely**, the consumption sacrifice is only postponed to a later date. This is when there is a requirement to pay off debt. Hence, **the later sacrifice** meaning that there is still a trade-off between investment and consumption.

3.2 Technological Change

Better arrows per hunter is called **technological change** as we have better productive resources to utilise. **Note that this does not mean more productive resources.** As we have better resources to use, we are more productive with them. Change happens through **innovation**.

3.2.1 Definitions

Beginning with some definitions:

- **Innovation:** introduction of new ways of doing more with less or the same amount. These efficiency gains are found in the **production process**. Innovation is usually knowledge shared freely in society.

Note that in modern economies, innovation is the outcome of:

- Basic research, mostly done in universities
- Research and Design (**R&D**), mostly done in firms

3.2.2 Economics of R&D

There are some key characteristics of innovation that must be recognised to show the thorny parts of R&D as it can sometimes cause barriers to technological change:

- **Upfront research costs:** Increase the burden of risk as there is a large requirement of upfront capital.
- **Non-Rivalrous:** One person's use does not exclude another person from using it. This means that if one firm creates an idea, without any protection around it, another firm can steal the idea and use it.

Hence, without any intervention, the costs for R&D are too high whilst the benefits are too low. We can see that with an equation below:

$$\begin{aligned}N &= \text{Net Benefit} \\R &= \text{Reward for Successful R\&D} \\P_R &= \text{Probability of Success} \\C &= \text{Cost of R\&D} \\P_C &= \text{Probability of Idea Stolen}\end{aligned}$$

Hence knowing that P_R is low and P_C is high, we have the equation:

$$N = R \times P_R - C \times P_C \text{ where } N < 0$$

3.2.3 Policy Solutions to the R&D Problem

Here are some solutions:

- Patents:
 - Intellectual property rights
 - Effective creation of monopolies over a certain good or service
 - Usually lasts 15-20 years
 - Opportunity for firms to make profit from their R&D
- Subsidies: reduced costs for R&D ventures conditional on their R&D performance

3.2.4 Economics of Basic Research

Basic research is about the type of activity generating positive externalities, **that is, a positive effect on a third party during the production or consumption of a good or service, in this case *research*.**

In terms of the funding:

- Subsidies are given by the government e.g. Economic and Social Research Council (ESRC)
- Stimulates research and research proposals
- Adds value to the economy without the pricing mechanism in place effectively 'shifting the frontiers of what is possible.'

3.2.5 Technological Change in Poorer Countries

Imitation makes a lot more sense than innovation in poorer countries. However, the issue is that **knowledge does not flow that easily**. Limited knowledge leads to a lack of accessibility. Successful imitation, however, shows miraculous levels of growth: **China and Japan being notable examples**

This issue of information dissemination is because new ideas contain two types of knowledge:

- **Explicit Knowledge:** formulas, blue prints, instructions
- **Tacit Knowledge:** nuanced knowledge like application with certain people etc. which cannot be communicated as effectively.

3.2.6 Sources of International Technology Diffusion

There exists two main ways of technological change moving around the world:

1. Foreign Direct Investment
2. Trade

Foreign Direct Investment (FDI):

- Foreign entity starts or acquires productive resources outside their home country
- Direct technology transfer through a literal implementation of the firms technology abroad

- Diffusion through imitation clusters, when the technology from an initial investment is taken up by aspiring entrepreneurs
- Competition with local, inefficient firms who need to learn/imitate/adapt or be pushed out of the market due to being priced out

Trade:

In trade there are exports and imports. Both contribute to technology diffusion:

- Imports:
 - Embodied technology e.g. importing IT systems
 - Pressure on local inefficient firms to adapt → same as FDI
- Exports:
 - Learning by exporting → learn to be more efficient and learn how to adapt to the demands of countries abroad
 - Market size increases → access to a larger market allows for diffusion of technology into developing countries simply because of broader exposure

3.2.7 International Tech Diffusion and IPRs

Question: Should poorer countries enforce intellectual property rights (IPRs) of rich-country firms?

There is a temptation to believe that not enforcing them can lead to cheap production by imitation however possible problems persist:

- It discourages FDI as there is no more profitability for these foreign firms to come into the developing market
- There would be adverse effects on rich country innovation as there is no longer an incentive to innovate. *This is based on the premise that firms are innovating to conduct FDI*
- Rich countries simply do not like it. This might result in a lack of trade and a souring of international relations which can subsequently cause a trade war

Yet, even with enforcement, a lack of enforcement could persist anyway due to the negligence of IPRs and Patents in developing countries. Hence, the issue appears to be much more complicated than black or white.

3.2.8 Embodied Technology

The distinction between capital accumulation or growth and innovation or imitation is conceptually useful. **However**, in practice, a lot of innovation or imitation is embodied in capital itself. Thus, the two often come in the same package. Investment is itself a source of technological change.

3.3 Management Quality

Management quality drives growth through putting people who are good at the right thing in the right place. This is done through **specialisation** and **comparative advantage**. Examples of high management quality:

- Adam Smith's pin factory → division of labour (specialisation)
- Henry Ford's assembly line → division of labour as well
- Outsourcing and global supply chains → utilising comparative advantage
- Gig economy → workers connecting through an information supply chain with an increased division in labour and level of specialisation

3.3.1 Definitions

Beginning with some definitions:

- **Specialisation:** focusing on one task and increasing the efficiency at which it is done.
- **Comparative Advantage:** whereby the opportunity cost to produce something for something else/someone is less than another entity. *One would say that a country has a comparative advantage if its opportunity cost to produce is less than another's.*

Further to that, organisational change can sometimes come as a form of technical change. You can do more with the same resources and it often requires some upfront R&D investment. An example would be something like **software to manage supply chains**, both organisational and technical.

3.3.2 The Indian Manufacturing Case Study

To test the real effects of management quality, consulting companies went into India to perform a test whereby control groups of firms were given no management consultants while tested firms were given management consultants to fix their most pressing issues over a few days.

Before:

- The manufacturing firms in India were very disorganised with dirty and poorly maintained machinery whilst equipment was lying across the floor.
- Yarn had no labels, order or damp protection. Further, it was piled so high, access was restricted in the factory itself
- Poor storage practices also made some stock unusable, requiring further treatment to be used again

After:

- Stock was organised and labelled
- Stock was also tagged and entered into the computer
- Factory was cleaned and maintained to a higher standard

3.3.3 Managerial Quality

Within a country, there is a big disparity in productivity among firms possibly due to the differences in managerial quality as a result of the different levels of organisation. There would be big gains from bringing up efficiency at the tail: *the lower end of the*

distribution is lagging far behind but can account for a lot of firms within the country.

Causes of Poor Managerial Quality:

- **Dynastic Management:** management of the firm kept within a family, not meritocratic and there is no guarantee of skill or will from future generations
- **Crony Capitalism:** Prevalent in low-income countries. Owners and managers are kept in a tight circle and benefits are accrued through political connections.
 - Shareholders can benefit due to their own connections
 - Productivity will be low due to mostly incapable management → again, not meritocratic but based on nepotism
- **State Owned Enterprises:** directly appointed by the government, low productivity due to failed selection process at some points

Entry Costs, Financial markets and Managerial Quality

- **Talented outsiders could:**
 - Buy out incumbents → but a lack of capital means they might not be able to, further, they can't judge their own talent compared to the market without experience
 - Enter with their own startups to compete them out of the market
- **High entry costs:**
 - Upfront production costs as capital raising is difficult
 - Licenses, permits etc. are barriers to entry
- **Poorly developed financial markets:**
 - Typically as a result of inefficient contract enforcement
 - This adds further difficulty to ensuring capital

Hence, it is obvious that Managerial Quality can be severely affected by a plethora of other factors. However, its contribution to growth can also be very large, especially at the weaker end of the distribution where basic practices - **ref: Indian Case Study** - have not even been implemented.

3.4 Human Capital Accumulation

More years in hunting school in our analogy translates to human capital accumulation. With more human capital, workers are intrinsically more productive and efficient and can apply their knowledge to technological, capital and managerial change. This is a cumulative effect from education that has knock-on effects on the facilitation of innovation and imitation.

3.4.1 Definitions

Beginning with some definitions:

- **Human Capital:** anything embodied in workers which makes them more productive, a form of internal development

The greatest focus of policy thus far has been **schooling** and **health** which aim to improve a persons ability to live and participate in the economy. Examples of foundations that have helped to develop this are:

- The Gates Foundation who aid in Malaria efforts and education
- The United Nations who have committees dedicated to raising the standard of living through education and healthcare especially in underdeveloped countries

3.5 Engine Interaction

We will discuss here how these growth engines interact and whether or not growth can come from a single engine. The latter first:

Ten hunters, 3 permanently on arrow-making duty. Initial endowment of 1 arrow power hunter. Over time, the change in GDP per worker will:

1. Increase
2. Decrease
3. Stay constant

Answer is 2. Decrease due to the diminishing marginal returns on capital. At some point, producing more capital leads to a plateauing increase in productivity.

Capital accumulation and GDP growth is shown through the average product of capital. This is known by $Average\ Product\ of\ Capital = \frac{GDP\ per\ Worker}{Capital\ per\ Worker}$

In our hunting village example this would translate to $APC = \frac{Deer}{Arrows}$. Gains from additional capital is known as the marginal product of capital which is known by the additional gain to product when there is a **unit increase in capital**.

3.5.1 Limits to Growth from Capital Accumulation

There are definitive limits to simply using investment as a driver for growth:

- The average product of capital declines due to the law of diminishing marginal returns
- The investment rate has a natural ceiling as it is limited by what is available i.e. it is difficult to invest beyond 100% of GDP
- Capital accumulation alone cannot sustain indefinite growth

From this we can see that:

- Capital accumulation depresses the average product of capital
- Innovation, organisational change and human capital accumulation boost the average product of capital
 - Hunting in a pack improves the productivity of all arrows
 - More trained hunters improve the productivity of all arrows

Hence all engines appear to complement one another to ensure that one engine does not depress the average product of capital entirely.

3.5.2 Engine Complementarity

Technical, organisation change and human capital accumulation keep the average product of capital falling even though capital per worker keeps increasing.

Although they might depress their own marginal productivity, this is offset by growth in the other engines. Think of the engines as multiplicative instead of additive:

$$Engine\ 1 + Engine\ 2 + Engine\ 3 + Engine\ 4$$

3.5.3 The Role of the State in Growth

The State plays a major role in the growth of the economy and they can facilitate it or hinder it depending on their policy. Below are ways in which the State can impact growth:

Fuel for Engines

- Investment in infrastructure which is a capital good
- Subsidies for R&D and basic research
- Investment into education and healthcare with good policy

Regulation

- Markets for goods and services are regulated by the state dictating what conditions people can operate under
- Regulation for labour and financial issues are regulated along the same lines
- International trade which is facilitated by the state through free trade or hindered by tariffs and trade wars

Rule of Law

- Laws to change the operation of companies e.g. GDPR in Europe
- **But** rigidity is also key for smooth business operation as predictability is key to confidence in operations
- Implementation of processes we can follow within a reasonable boundary

3.5.4 Corruption and Growth

Another issue to consider when thinking about growth is corruption. Here are some reasons why:

- Saps incentives for innovation, imitation and investment if corrupt officials target successful entrepreneurs. This is due to the burden of bribe payments which means less money to innovate or incentivise productivity.
- Creates barriers to entry for outsiders if those inside use corruption to buy protection, privileged treatment or judicial bias which means less incentive to innovate or even try in the first place
- Deprives government of funds for infrastructure, education, administration of justice due to embezzlement. This means less investment into the engines of growth within the economy by the government

3.6 Growth Engines: Appendix

Find related materials here. Some may be repeated from other appendices.

3.6.1 Formulae and Definitions

- **Investment Rate:**

- A measure of the sacrifice an economy makes of current consumption for a greater level of future consumption.
- **Formula:** $Investment\ rate = \frac{Level\ of\ investment}{GDP}$

- **Average Product of Capital:**

- The amount of product that you gain from total capital invested into a worker.
- **Formula:** $Average\ Product\ of\ Capital = \frac{GDP\ per\ Worker}{Capital\ per\ Worker}$

- **Δ in Capital per Worker:**

- The change in capital that a worker has, averaged across the whole economy.
- **Formula:** $\Delta Capital\ per\ worker = investment\ rate \times GDP\ per\ Worker$

- **Growth Rate of Capital per Worker:**

- The growth in capital that a worker has, averaged across the whole economy.
- **Formula:** $Growth\ Rate\ of\ Capital\ per\ worker = investment\ rate \times (GDP\ per\ Worker / Capital\ per\ worker)$

4 Economic Fluctuations

This section will dive into the economic fluctuations commonly seen within an economy. There exists two types of fluctuation in the economy:

- Aggregate Demand Shocks
- Aggregate Supply Shocks

These can also be talked about as:

- Tailwinds → pick up in growth
- Headwinds → shock slowing down rate of growth

4.1 Demand Shocks

We will first discuss demand shocks in the economy.

4.1.1 GDP Composition

Recalling the equation

$$GDP = C + I + G + (X - M)$$

From here we can see the breakdown:

- **(C)onsumption:** goods and services bought by households
- **(G)overnment Spending:** goods and services bought (or produced) by the government
- **(I)nvestment:** investment goods bought by firms
- **(E(x)ports):** goods, services and investment goods sold abroad
- **(I(m)ports):** goods, services and investment goods bought abroad

With these we can move on to how this composition can cause the actual shock.

4.1.2 Aggregate Demand

Anything that suddenly causes:

- A change in government spending **G**
- A change in *desired* investment **I**
- A change in *desired* investment **C**
- A change in net exports **NX**

Following that, we can see some examples of demand shocks:

- **G:**
 - Wars → planned spending increases due to necessity of building and providing materials
 - Changes in ideology → austerity in government spending, reducing **G** by a large amount

- Fiscal crises, such as Venezuela and hyperinflation and further Sovereign Debt Crises

- **I and C:**

- Changes in taxes → increases in income tax decreases ability to consume while increases in corporate tax will reduce investment - the counter case is probable too
- Changes in wealth → anticipation in increasing wealth and its tangible effects on how one would spend. If you think you are wealthy, your propensity to spend increases as well
- Psychological changes (Keynesian animal spirits) → anticipation, proclivities or behavioural reaction that is unpredictable and ultimately reliant on the individual

- **X - M:**

- Changes in exchange rates → a result of currency strength
- Foreign demand shocks → they could reduce or increase exports and imports depending on what the shock is. If it's negative, exports are likely to reduce while imports, due to lower production, might also reduce

However, one has to be careful on the causality of aggregate demand shocks on GDP:

$$GDP = C + I + G + (X - M)$$

This is not a causal relationship

You have to question what makes firms respond to the change in AD as GDP is not simply caused by planned spending. There is a missing step as well that might not be identified in the equation.

4.1.3 Narrative of the Aggregate Demand Shock

With the previous in mind, let's construct a narrative to show how an aggregate demand shock actually works:

1. Consumers decide to spend 10
 - They have increased confidence
 - They have an improved ability to pay
 - They have an increased level of wealth
2. This leads to an increase in aggregate demand by 10% as planned spending has increased
3. Marginal costs go up
 - Marginal costs of production increase
 - This is through expansion of production due to demand increasing
4. Prices go up
 - Since marginal costs increase, this is translated into price:
 - $MC > P \therefore P \uparrow \therefore MC \uparrow \text{ until } MC = P$

5. Increase is proportional i.e. 10% increase in prices
 - Price increase will match demand increase
 - Equilibrium is a situation where the economy ends up in after the shock

The price increase matches the demand increase because:

- Consumers are happy as they are spending 10%
- Firms are happy as marginal cost is up 10% as it depends on prices and wages
 - Same amount of materials and workers
 - Wages are 10% higher as well due to price increase, all
- Marginal revenue is up 10% as it is the price, $MR=MC$

Lessons from the narrative:

After an aggregate demand shock:

- Quantities change in the same direction
- Prices (gradually) adjust in the same direction
- After prices have adjusted, no effect on quantities, a movement back to its original position

The size and duration of effect on quantities depend on speed of price adjustment:

- A fast price adjustment has a small impact on quantities
- A slow price adjustment has a big impact on quantities

We can see that price changes, however, vary heavily between firms. Below is a table of collected data from the University of Chicago by Blinder (1994):

Frequency	Percentage of Firms
Less than one	10.2
Once	39.3
1.01 to 2	15.6
2.01 to 4	12.9
4.01 to 12	7.5
12.01 to 52	4.3
52.01 to 365	8.6
More than 365	1.6

Hence, we can see that the price change which is most popular, **once**, shows the relatively infrequent changes in price that a firm puts out. It can be argued that due to this low infrequency, the aggregate demand shock is actually absorbed by firms.

Explanations for Price Stickiness

Here are some explanations why prices might not change as frequently as one might think, i.e. in alignment with the **frequency of aggregate demand shocks** people experience.

- **Menu costs:** there are costs associated to changing the price such as physically having to print new menus

- **Information costs:** there is an opportunity cost of time to get and process information on what the right price to put is
- **Strategic considerations:** perhaps being the first to move on price might be bad, especially increasing, as market share can go down drastically if a lot of other substitutes are in place
- **Wage rigidity:** wages change very rarely, typically yearly, so price adjustment would not fit wages. Wages \rightarrow Demand \rightarrow Prices. Thus rigidity begets rigidity, if prices were to change, consumers might switch or not purchase

4.2 Counter-cyclical Policy

Goals of counter-cyclical policy:

- Counter negative aggregate demand shocks to prevent recessions
- Counter positive aggregate demand shocks to prevent excessive inflation

There are two main types of counter-cyclical policy:

- **Fiscal Policy:**
 - Changes in government spending (including transfers) and taxes
 - Run by the treasury (though this is country dependent)
- **Monetary Policy:**
 - Purchases and sales of financial assets, setting of statutory i.e. required interest rates
 - Run by the central bank

4.2.1 Fiscal Policy

Here are some concepts related to **fiscal policy**:

- **Government Spending:** goods, service bought or produced by the government along with transfers such as benefits and interest paid
- **Government Revenues:** from mostly taxes
- **Deficit:** $Spending > Revenues = \Delta Debt$
- **Surplus:** $Spending < Revenues = -\Delta Debt$

Fiscal policy also has a dual role:

- A source of demand shocks: the recent austerity programme in UK
- A tool to counter other demand shocks: increase in deficit in recessions to increase spending, fiscal stimulus policies in 2007-2009

Further to that, there is the concept of the fiscal multiplier: the change in GDP due to a £1 change in the deficit. This multiplier is generally thought to be **greater than 0 and less than 1**. Below is a sample question:

Suppose the government spending multiplier is less than 1. $C+I+NX$ ---- when G increases:

1. Increases
2. Decreases

Answer is 2. Decrease due to GDP remaining constant as $Y = C + I + G + (X - M)$. This means that $C + I + (X - M)$ will reduce to balance G increasing.

Crowding Out: However, given the use of fiscal policy, crowding out is also a major issue:

- **Definition:** The crowding out effect is an economic theory arguing that rising public sector spending drives down or even eliminates private sector spending. (Kenton 2019)
- Some of the increase in spending mobilises idle resources but some diverts resources from other uses. *The multiplier is larger when there are many idle resources*
- Some of the tax cuts are spent on goods and services but some are saved. *The multiplier is larger when people have a large propensity to consume*
- Fiscal policy is most effective in severe recessions **i.e. the multiplier > 1**

Hence, crowding out means a reduction in private spending despite the government's initiative to increase spending overall. This is shown by saving from reduced taxation or shifting resources instead of mobilising them. There is minimal crowding out when there are many idle resources but a significant crowding out when significant tax cuts could lead to savings.

There are limits to **Expansionary Fiscal Policy:**

$$Deficit = \Delta Debt$$

Deficit adds to the debt:

- If the deficit is $+ve$, $\Delta Debt$ is $-ve$
- If the deficit is $-ve$, $\Delta Debt$ is $+ve$

However, note that the deficit is still beneficial in some cases. As we discussed before, the increase in borrowing can be used to fund capital goods that might increase future consumption greatly. Just using debt in moderation is required.

Thus, here are some **Golden Rules for Fiscal Policy:**

- Run a deficit in recession and a surplus during the boom. **Fiscal Policy should be countercyclical where possible**
- **Balance the budget on average**, this comes from following the previous advice
- **Do not run a balanced budget all the time!** Governments need to know how to be contextual with their balance sheet to promote growth or slow it in anticipation of a recession

4.2.2 Monetary Policy

We now move onto Monetary Policy. This is seen to be the job of central banks: the Federal Reserve: **The Fed**, the Bank of England: **BoE**, the European Central Bank: **ECB**, the Bank of Japan: **BoJ** and so on.

Their goals are to **counter demand shocks** and this is done through:

- Monetary policy to affect **interest rates**: the cost of borrowing and reward for saving
- Interest rates then affect Consumption and Investment

Interest Rates:

- Many forms of borrowing exist in the economy
 - Firms and Households borrow from banks
 - Households borrow by using credit cards
 - Firms and governments borrow from the public by issuing bonds
- Interest is the compensation received by the lender from the borrower
- The interest rate is the **per-unit-value** compensation

Interest rates also tend to move together such that if the interest rate on one form of borrowing goes up, interest rates on other forms of borrowing tend to go up as well. Here are some examples:

- Interest rate on government bonds go up
- Demand for corporate bonds go down
- Interest rates on corporate bonds go up

From above, if LSE is paying $x\%$ interest and the government is paying $(x + 1)\%$ interest, borrowers have the option to arbitrage unless the lender sees this disparity.

What is a Central Bank? The central bank is mainly two things:

- The commercial banks' bank, existing as a regulatory institution
 - Offers deposits to commercial banks (bank reserves) → like a current account for the bank itself
 - Lends to commercial banks (discount window, repos etc.) → loans from the central bank like overdraft, drawing from a credit line
- Monopoly supplier of legal tender → preserving and regulating the value of money, having the technology to create legal tender that is unforgeable

Policy Rates The central bank has a crucial role in setting the policy rates:

- Policy rates are interest rates set directly by the central bank
 - Rates on bank reserves
 - Rates on loans to commercial banks
- By changing policy rates, central banks can affect all other rates in the economy

An example of how this widespread effect works is done below:

Take the bank's current policy rate to be $x\%$. In the case that the bank decides to reduce this interest rate to $(x - 2)\%$, we will see that the interest rate on central bank loans goes down. Financing for commercial banks becomes cheaper as it is effectively cheaper to borrow since the interest payment required is less. This means that commercial banks require lower interest rates to lend to firms and households.

Having had a look at the policy rates, let's see the interactions policy rates have with components of GDP:

- Interest rates and **I**:
 - Cash-poor firms: cost of borrowing since high interest means higher costs of debt and low interest means cheaper cost of debt
 - Cash-rich firms: opportunity cost since high interest provides incentive to lend to make cash and low interest means an opportunity to invest elsewhere for higher returns, potentially their own company
- Interest rates and **C**:
 - Cash-poor individuals: cost of borrowing since high interest means higher costs of debt and low interest means cheaper cost of debt e.g. purchasing a house
 - Cash-rich individuals: uncertain of the borrowing aspect but potentially used to invest in different areas

4.2.3 Economic Activity and Policy

Natural Level of Economic Activity: the level to which the economy gravitates back after a shock. Price adjustment makes sure that this happens. There is a center of gravity that economy tends to due to the refined outlook people have after a shock. Look at the below picture to understand the fluctuation and **natural level** the economy gravitates back to:

Counter-Cyclical Monetary Policy

Examples of this type of policy is shown below:

- Lower interest rates when contractionary aggregate demand shocks take the economy below the natural rate of economic activity
- Increase interest rates when expansionary aggregate demand shocks take the economy above the natural rate

However, this policy is very difficult to implement. This is because it is very hard to tell whether the economy is **at, below or above the natural rate of activity**. Further to that, policy mistakes have a real risk:

- Monetary (and fiscal) **expansions generate inflation when the economy is at or above the natural rate of output**, or when they push the economy above the natural rate
- Monetary (and fiscal) **contractions cause recessions when the economy is at or below the natural rate of output**, or when they push the economy below the natural rate

The Effective Lower Bound

To add further complexity to interest rates, we will discuss the effective lower bound.

Definition: The point at which interest rates will stop having a tangible effect and the rate below which it is difficult to go.

Before we go into explaining the complexities of it, here are some key terms to recognise:

- **Negative Interest Rates:** incentive to borrow and hoard cash at a very negative point of interest
- **Minimum Interest Rate (ELB):** cost of storing cash exceeds the gains from borrowing and hoarding cash

Hence, when interest rates are at the ELB, conventional monetary policy becomes unfeasible as people are not hoarding cash due to storage costs but are not willing to spend anything either. Until recently it was thought that the ELB was 0, also known as the Zero Lower Bound (ZLB) but empirical evidence has shown that Central Banks can go lower, a little into negative interest rates, to stimulate spending. Examples include:

- Japan at -1%
- Sweden at $-.75\%$
- ECB at $-.4\%$

There are ways of getting around the effective lower bound such as:

- Abolishing paper currency and predominantly using debt cards etc. \rightarrow lose on negative interest rates in deposit account, this would not work on cash as it is tangible, unable to borrow or store notes and coins which means no storage and hoarding of money
- Abolishing large denominations \rightarrow storage space required increased as a result of only small denominations existing which increases the cost of handling cash

Thus, the effective lower bound is

4.2.4 Unconventional Monetary Policy

This brings us to our discussion on unconventional monetary policy, sometimes labelled as **Quantitative Easing:** purchasing a large amount of long-dated bonds to inject money into the economy to stimulate it.

To understand how this works, we will first need to understand the complexities of a bond:

Key facts about Bonds:

- Simply a vehicle through which one can borrow money
- They can be issued by the government or firms.
- Bonds issued by the government are usually labelled as **risk free bonds**.
- The bond purchaser pays, known as the **lender**.
- The issuer of the bond, such as the government or firm, is known as the **borrower**, and is committed to paying coupons of interest payments during the time to maturity.
- The time to maturity is the time taken for the bond to be fully repaid and can vary wildly from months to up to 30 years i.e. the time taken to repay the initial lump-sum amount
- At the time of maturity, the lender will be paid a certain amount of interest on top of the initial lump-sum that they would be given back at the beginning of the bond issue.

And on top of that, a bit of financial terminology through looking at the **Yield Curve** which is presented by a simple picture below:

It slopes up because of the concept called **Liquidity Premium**: where lenders require extra compensation for locking money in → no access in case of emergency or opportunity, unless sold on secondary markets.

Now, establishing our yield curve, we can begin to analyse how the central bank can affect it with **conventional monetary policy**. This is done through policy rates which affect the most shortest of terms such as deposits, which can be taken out at any time and interbank loans which typically last one or two days. Thus if the central bank lowers policy rates, we can see the shift in the yield curve below:

Since policy rates are very short term, the maturity is right next to the origin. Further, knowing that interest rates move together, we see a shift downwards at all maturities following this trend. However, this is not the problem we are facing at the ELB. What we are seeing at the ELB is an inability to change the policy rates as shown below:

As shown in the picture above, there is no scope to change the policy rate as it is at the ELB. Thus, unconventional monetary policy aims to flatten the yield curve by dragging it down directly at the later maturities to push the yield curve to a new position as shown below:

This works through our relationship between Bond Purchases and Interest Rates:

- Interest rates fall if demand for bonds exceeds supply \rightarrow this is because more people want to lend money thus those borrowing can bargain for a lower interest rate

- Interest rates increase if supply of bonds exceeds demand → this is because more people want to borrow money thus those lending can bargain for a higher interest rate

Since the central bank is taking bonds out of the market, they artificially cause the supply to fall relative to demand. This makes interest rates fall as we have argued above which makes it easier to borrow. Since interest rates effectively fall down, this affects consumption and investment, stimulating them and subsequently the economy.

However, as a result of this, a lot of central banks balance sheets have exploded due to the amount of long-dated assets that they now hold. To affect interest rates, one must remember that you need to deal in the billions and trillions to move rates around. **The question of how the central banks will get rid of these assets remains.**

Does Quantitative Easing Work?

Compared to conventional monetary policy, the data available for QE is basically non-existent. However, the effects of QE have definitely placed us in a better position than what we would have been. Not only in economic terms but the uplift in supply of money in the system also provided a psychological boon that prevented our mindsets to go into a deeper recession. Therefore the answer is: *Who knows? But it's better than nothing.*

4.3 Supply Shocks

Now we move onto the topic of Supply Shocks. This is any shock in the economy to do with the supply side such, usually production.

4.3.1 Examples of Supply Shocks

We will begin with some examples:

- Accelerations or decelerations in technical change → technological change at a rate that is vastly different to the standard level of technological change can lead to large efficiency gains in production providing a supply shock
- Changes in the costs of materials → costs which are passed onto production, such as oil, can implicitly control the level of supply as they are inputs into production. Firms have to decide on the level of supply they want to produce and the costs of these inputs impacts them greatly

4.3.2 Supply Shocks and Prices

Supply shocks have the opposite implications to demand shocks. When there is an expansionary supply shock, there tends to be a fall in prices as costs of production are usually decreasing. When it's contractionary, prices tend to increase as costs of production increase as well. Quantity and prices move in the opposite direction from a supply side perspective. If the quantity of supply increases, prices tend to fall **note that this is already different from demand.**

Further, supply shocks add to the central banks' dilemmas:

- One cannot tell where the economy is relative to the natural rate when the supply shock occurs
- Contractionary supply shocks reduce quantity and increase price, seen to be the worst of both worlds
- Demand cannot be boosted by reducing interest rates as price levels will be exacerbated

An example to illustrate this dilemma is when a contractionary supply shock is misdiagnosed as a contractionary demand shock. An attempt at expansionary fiscal policy will have the average price level of goods shooting through the roof.

4.3.3 The Relative (UN)Importance of Supply Shocks

Yet, supply shocks do not seem to matter as much and here are some examples why:

- Implausibility of technological regress → we don't forget the progress that aids production
- Many cycles with no clear shock to material prices → there's an inability to identify absolute causes to shocks
- Prices are procyclical on average → prices move usually in the same direction of the cycle while supply shocks are counter-cyclical

4.4 Economic Fluctuations: Appendix

Find related materials here. Some may be repeated from other appendices.

4.4.1 Formulae and Definitions

- **GDP:**
 - The amount of goods and services produced in an economy in a year.
 - **Formula:** $GDP = C + I + G + (X - M)$
- **Deficit:**
 - When government spending exceeds government revenues.
 - **Formula:** $-\Delta Deficit = Spending - Revenue$
- **Surplus:**
 - When government revenues exceeds government spending.
 - **Formula:** $+\Delta Deficit = Spending - Revenue$

5 Inflation and Deflation

Now we begin on the topic of inflation with some **definitions**:

- **Inflation**: the sustained increased in the level of prices
- **Inflation Rate**: the percentage change in the level of prices
- **Consumer Price Index**: measures the cost of buying a representative bundle of consumer goods and services year on year
- **Hyperinflation**: when inflation exceeds 50% per month
- **Deflation**: the sustained decreased in the level of prices, where people are spending less in the economy with the expectation of further price drops

5.1 Inflation

We will begin with moderate levels of inflation. A key example of moderate inflation would be the **United Kingdom**.

5.1.1 Absolute versus Relative Prices

We will begin with some conceptual groundwork:

- **Absolute price** changes are merely a change in the units of measurement → if there is a 10% absolute price change, everything will be 10% more expensive
- **Relative price** changes convey information on scarcity or abundance and likes or dislikes → scarcity or abundance of one thing relative to another will change its relative price i.e. if something is particularly scarce, its price will increase, if something is liked a lot, then its price will increase relative to other goods and services

We want relative prices to tell producers what to do so that resource allocation is optimised in a way.

Hence, inflation is a problem not because it changes absolute prices, if that were the case, everyone would still have the same purchasing power as all things, including wage, increases simultaneously. It is because of changes in real or perceived relative prices that inflation can be problematic. **It interferes with the information contained within relative prices.**

5.1.2 Inflation and Relative Prices

Inflation forces firms to change their price. This might be due to costs of wages increasing or costs of raw materials increasing. Remembering that the frequency of price changes are different from firm to firm, this creates a relative price change as they do not change simultaneously. **Relative prices then reflect timing of firms' decisions rather than on scarcity/abundance or like/dislike** → this creates an inflationary environment that does not send signals related to our previous factors. Firms are forced to change prices when they get a chance messing up our information contained within prices.

Example: A firm issues a new catalog each January. As the general price level rises throughout the year, the firm's relative price will fall.

The above is called a **real relative change in price**.

This means that consumers and firms may also mistake absolute price changes for relative price changes. This is not a real relative change!

Example: Consumers may feel their purchasing power is falling when it is not. There is a mental disconnect between their own wage increase and the absolute increase in prices. They think themselves as poorer when they are not which is a hit to their welfare, a direct negative psychological effect.

It makes people unhappy and it makes them decide on things incorrectly like cutting their consumption even though their purchasing power has remained the same. Hence, the allocation of resources is adversely affected.

5.1.3 Inflation and Uncertainty

The higher the inflation rate, the more variable and unpredictable it becomes i.e. **increased volatility**.

- Higher uncertainty, so risk-averse people are worse off → there is a social cost and direct psychological cost inlaid within this
- Risk averse people forego potentially profitable opportunities → consumption and investment are likely to be reduced
- More time, resources and efforts are devoted to financial planning → this means that resources are diverted away from better productive activity just to plan ahead, a simple misallocation of resources

Here is an example of this variability:

The Inflation Scenario:

Two scenarios:

1. Inflation at 2% has a probable range of 1% to 3%
2. Inflation at 10% has a probable range of 6% to 14%

This means a large variability in the range of inflation. Using the example of lending money where we charge a 3% premium on the loan so if inflation is at 0% we charge 3%, if inflation is at 5% we charge 8% and so on. So if we have a loan with inflation at 10%, we get a premium of 13%.

However, noting our variability from above, we might be losing out in purchasing power by 1%, getting back less from our loan, if inflation goes to 14%. Hence, the risk averse would not decide to invest or consume as much in a high inflation market.

5.1.4 Benefits of Moderate Inflation

Here are some benefits to consider:

- Stay away from deflation which is an insidious problem!
- Stay away from the ELB by putting up higher interest rates at normal times which means we are further away from the ELB and more able to ratchet down if required

Note that 0% inflation means that on average, half the time we are in *-ve* inflation which could lead to persistent deflation in the future. We are aiming for something a bit higher, a lot of Central banks target around 2%.

5.1.5 Bringing Inflation Down

Question: why are Central Banks so anxious about having inflation above their target number?

Answer: it is very costly and difficult to bring inflation back down.

Inflation has a major impact on people's forward looking pricing decisions. When producers set prices, they need to get right their forecast. If they are lower than actual inflation, that is costly to them. If they set it higher, their goods and services would become uncompetitive.

If you're coming from 4/5 years of high inflation, you'll naturally expect high inflation the next year. Hence, this expectation might become self-fulfilling. Prices are set 10% higher, wages are asked to be 10% higher etc. Inflation is baked into the forward looking pricing decisions i.e. it is the **expectation or the norm**.

Argentina is stuck in this situation. This is why Central Banks are worried about these inching upwards of inflation rates. The solution to this issue is to engineer a recession with a **sharp increase in interest rates**. However, this is a very costly method → political upheaval, unemployment in crazy numbers and psychological damage.

5.1.6 Inflation Targets

This shows that expectations are incredibly important to success. The most successful Central Banks are those who know how to manage expectations. One method of managing expectations and creating credibility is the public announcement of inflation targets. Here are a couple examples:

- Bank of England (BoE): 2% inflation target
- European Central Bank (ECB): < 2% inflation, very close to 2%

These inflation targets are a very clear deal that is made with the public. Even with the fluctuations around it, the trend is around 2%.

5.2 Hyperinflation

Knowing our standard definition: inflation which exceeds 50% each month, we can now discuss the consequences of Hyperinflation:

- Relative prices lose all meaning
- Planning is impossible because the future value of money is too uncertain and variable
- There is a focus on protecting purchasing power where nearly all effort goes towards → daily routine involved running to get groceries when getting paid twice a day, even a minute makes a difference to purchasing power
- Production declines as a result of this distracted activity

5.2.1 What Causes Hyperinflation?

Here is the causal explanation:

- Hyperinflation is caused by excessive currency creation
- Government printing money causes the price level to rise
- If money is printed rapidly enough, the result is hyperinflation

Below are a few examples of hyperinflation:

Country	Period	CPI Inflation (%)	Money Supply Growth (%)
Israel	1983-85	338%	305%
Brazil	1987-94	1256%	1451%
Bolivia	1983-86	1818%	1727%
Ukraine	1992-94	2089%	1029%
Argentina	1988-90	2671%	1583%
DRC	1990-96	3039%	2373%
Angola	1995-96	4145%	4106%
Peru	1988-90	5050%	3517%
Zimbabwe	2005-07	5316%	9914%

What causes excessive money printing?

- Large budget deficits → where government spending is far greater than government revenue
- No room or political will for fiscal adjustment → can't reduce government spending and can't increase taxes
- No access to capital markets → international lack of confidence in the economy

5.2.2 Ending Hyperinflation

Here are some ways in which one can reduce hyperinflation:

- Fiscal Reform
- Monetary Reform

Fiscal Reform

Government has to become less dependent on money printing. This can be done thorough fixing the deficit by reducing the large disparities present by introducing higher taxes and lower government spending. Possibly, the ability to attain funding from abroad might be a solution as well.

Monetary Reform

The government can make sure that there is a fixed rate of Money Supply growth. This will change **expectations**, a key factor, in line with reduced growth. However, this is not observable to people hence it is hard to be fully credible. Further to that, you can set an **inflation target** which will show some sense of credible commitment. However, this is also a statistic as well which is produced by the government. If the government has no credibility then it would not work out as well. A lot of successful cases of solving hyperinflation happens through a pegging of the currency. Here there is a credible commitment to keeping the currency's value → if you print too much, the currency depreciates, if you print too little, it appreciates. This is a tangible and observable change so credible commitment is present.

Central Bank Independence

This is also another solution to ending hyperinflation. This is to provide **operational independence** which isolates monetary policy from fiscal policy. For example, **Venezuela's Central Bank is not independent**. Yet, the government still decides the overall framework of what the Central Bank will do. Just the day to day decisions are not interfered with by the government.

5.3 Deflation

Now we begin an overview of deflation. Here are the key concerns with deflation:

- It causes an incentive for consumers to **delay purchases** as prices are expected to fall in the future → if the consumer does not have an immediate need, they can delay their purchase to save
- Further, it can increase debt burdens as the value of money is depreciating while the value of debt is more → this makes debt more expensive to pay
- Both can exacerbate recessions and lead to a vicious cycle

Recalling our equation $Y = C + I + G + (X - M)$, consumption, through consumers holding back purchases, and investment, through debt becoming more expensive, is likely to fall as a result of deflation

5.3.1 Fighting Deflation

The solution seems simple: print lots of money. This:

- Decreases the value of money
- Induces reasoning to spend now rather than later before value of money is reduced too much

5.4 Inflation and Deflation: Appendix

Find related materials here. Some may be repeated from other appendices.

6 Unemployment

The concept of unemployment is central to living standards. This is associated not just with income but psychological and social well-being as it provides a sense of security and purpose. We begin with some key concepts in unemployment:

- **Employed:** working at a paid job
- **Unemployed:** not working but actively looking for a job
- **Labour Force:** all employed and unemployed people, these are those who are already active or willing to work
- **Rate of Unemployment:** the percentage of the labour force that is unemployed

Observations show that:

- The unemployment rate is **counter-cyclical** → it rises when there is a recession and falls when there is a boom
- The long-run average varies a lot from country to country

We also have the concepts of **Cyclical** and **Natural** unemployment:

- Natural Rate of Unemployment (NRU): the normal unemployment rate the economy experiences when it is neither in a recession nor a boom
- Cyclical Component: the difference between the actual and the natural rate → the cyclical rate fluctuates away from the NRU due to shocks which are deviations from the norm

Therefore, that takes us to our analysis of unemployment. Our previous discussion of economic fluctuations helped us understand the cyclical component. This section will focus on what determines the NRU and ask why it varies across countries.

6.1 A Basic Model of the NRU

Through Chris Pissarides, a Nobel Prize Winner, we can model the natural rate.

Lets begin with the components of the model:

- L = Number of workers in labour force (fixed)
- E = Number of employed workers
- U = Number of unemployed workers

Unemployment rate: $\frac{U}{L}$

6.1.1 Labour Market Flows: Separations

This flow shows employment to unemployment. Reasons causing this could be as follows:

- Dismissals, redundancies or firm closures → firm side
- Quits → worker side

For separations, we have the rate of job separation:

$s = \text{rate of job separation}$

This is the fraction of employed workers that become separated from their jobs in a given period e.g. $s = 1\%$ per month

This is FLOW 1.

6.1.2 Labour Market Flows: Matches

This flow shows unemployment to employment. Conceptually:

- Search for workers as firms \rightarrow matches from the firm side
- Search for firms as workers \rightarrow matches from the worker side
- **This whole process takes time and effort**

$f = \text{rate of job finding}$

This is the fraction of unemployed workers that find jobs in a given period e.g.
 $f = 20\%$ per month

This is FLOW 2.

6.1.3 Transitions between Employment and Unemployment

From above, we can put **FLOW 1** and **FLOW 2** into a simple visual model.

So we can move onto computing the natural rate. From deduction:

- During booms flows out of unemployment exceed flows inwards
 $f \times U > s \times E$ thus unemployment is below the NRU
- During recessions flows into unemployment exceed flows outwards
 $f \times U < s \times E$ thus unemployment is above the NRU
- At the natural rate, flows in roughly equal flows out
 $f \times U = s \times E$ thus unemployment is at the NRU

From there we can begin to solve for the natural rate:

$$s \times E = f \times U$$

Knowing that $E = L - U$

$$s \times (L - U) = f \times U \text{ where } L \text{ is a constant}$$

Rearranging to get $s \times L = (s + f) \times U$

$$\text{Hence: } \frac{U}{L} = \frac{s}{s+f} = NRU$$

We can see from this that if s is high and f is low, we would have a higher NRU.

From that, we can draw an example:

Each month:

- 1% of employed workers lose their jobs $\rightarrow s = 0.01$
- 19% of unemployed workers find jobs $\rightarrow f = 0.19$

From that, we can use our formula $\frac{U}{L} = \frac{0.01}{0.01+0.19}$
Hence, $NRU = 0.05$ or 5%

6.2 Labour Market Policies and Institutions

Some separations and delays in job finding are inevitable and so is unemployment. However, policies and institutions can improve the effectiveness of job search, the incentives to both separations and searching and the willingness of firms to open vacancies. here are some examples:

6.2.1 Active Labour Market Policies

Government programs to help workers search (increase f)

- Government employment agencies: disseminate information about job openings to better match workers and jobs; help with CVs and interviewing skills etc.
- Public job training programs: help workers displaced from declining industries get skills need for jobs in growing industries e.g. technology now
- Conditional unemployment benefits: incentivise worker search by making unemployment insurance dependent on job search efforts

6.2.2 Unemployment Insurance (UI)

The basic idea of UI is that it pays a part of a worker's former wages for a limited time after the worker loses their job. The government usually helps make up for the loss of income. It helps for the following reasons:

- It reduces the hardship of unemployment both in an economical sense and psychological sense
- By allowing workers more time to search, UI may lead to better matches between jobs and workers
- Better matches means higher productivity and incomes due to a more efficient allocation of resources
- It may also support aggregate demand in recessions by preserving the spending power of those unemployed as a result of the recession

However, UI also has a dark side to it as well. This is because of the following reasons:

- UI increases **search unemployment** i.e. those unemployed because they are searching for their next opportunity

- UI reduces the opportunity cost of being unemployed which subsequently reduces f due to the lesser amount of stress associated with unemployment which might disincentivise greater efforts to find a job
- Studies also state that the longer a worker is eligible for UI, the longer the average spell of unemployment
- The government also has to provide the level and duration of UI so as to find the right balance between cost and benefits i.e. enough UI to be psychologically and economically support but not so little that it'd disincentivise effort for f

6.2.3 Employment Protection Legislation (EPL)

Analogy for Unemployment:

Increasing the cost of divorce will result in ____ unmarried people.

1. More
2. Fewer
3. Hard to tell

The answer is 3. Hard to tell as people will stay married but also people will be reluctant to get married. Hence, the calculation here is difficult.

The logic of the example above is applied here. This is because of the costs of firing that we can see as analogous to the costs of divorce. For example, **the US Model has a fire at will policy**. Many other countries, however, have set policies that make firing workers more costly through controls such as **higher mandatory severance pay**, which is the amount paid to employees on separation, and **spelling out specific conditions for severance**, which means that there is a requirement for valid reasons for separation such as grave firm distress or grave misconduct by employees. The aim of EPL is to **protect workers from excessive insecurity and arbitrary decisions**. Otherwise the unequal power relationship that exists between employer and employee would be too one sided.

Below I illustrate the relationship between EPL and Unemployment:

- In principle, the relationship is ambiguous
 - Lower s means a reduced separation rate
 - Lower f means a reduced finding rate due to employers not willing to risk a costly severance
- However, a casual observation shows that: countries with high EPL tend to have higher unemployment. This is open to debate though as it might just be a correlation and not causal whatsoever

Politics of EPL

There are conflicts between insiders and outsiders. Here are the definitions for both:

- **Insider:** those who have secure jobs and are happy with a high level of EPL
- **Outsider:** those who do not have a job, are searching for one and are not happy with a high level of EPL

The issue between these two contenders is that the insiders are politically more powerful. There is an implicit insider bias where they have an ability to strike and are effective at lobbying against EPL change.

6.2.4 Wage Setting Process

Many wages are not set on a spot market. There are national sectoral contracts which means wage increases with fewer new jobs. Further to that, the disproportionate weight on interests of insiders results in wages too high to encourage job creation whereby f is low. I illustrate the union and representative employers process below in the negotiation process:

Unions represent employees who are **currently employed**. Employers represent themselves in the same process and do not care so much about the unemployed. This means that they come to agreements based on those employed and this means probable wage increases reducing opportunities for firms to create new vacancies due to the costs associated with them.

High EPL exacerbates insiders focus on wage increases to the detriment of outsiders. The higher the EPL, the greater the impact of centralised wage setting as EPL can allow unions to push for big increases. This creates a vicious cycle where **EPL effectively locks in the insiders interests at the expense of those who are not securely employed**.

6.3 Dual Labour Markets

We introduce this concept of a **Dual Labour Market (DLM)** to show some alternatives to EPL. Listed below are a few examples:

Temporary Jobs without EPL

The premise here is that you hire an employee for a trial period. After a few months, the firm needs to make a decision to either hire them fully, and subsequently employ all the EPL legislation and so on, or fire them straight away. Below are some pros and cons:

- Benefit: Unemployed get some work some of the time. This means immediate money and employment
- Disadvantage: There is no incentives for firms to invest in workers and no incentives for workers to invest in firms since they can fire and hire liberally. This means a lack of human capital accumulation (an engine for growth) and a lack of training

The result of this means that middle aged workers are secure in permanent jobs but **young workers are stuck in a loop of unemployed to employed** with no human capital accumulation. This means that they do not build credible skills to work with in the future.

Gradual EPL Scaling

Recent reforms in Spain and Italy build contracts which have a gradual scaling of EPL. This allows for gradual investment into human capital and makes the job more secure

over time. This provides flexibility in the short term for firms whilst providing security for workers down the line if they are committed and do well in their job.

6.4 Payroll Taxes

The effect of payroll taxes, which we can define as **an amount of tax paid by the employer based on the employees wages**, is an increase in the cost of labour. Although it is **an important source of government revenue in many countries**, it has a detrimental affect on unemployment, worsening it as the increased cost of labour means less vacancies are created by firms. This ultimately translates into a potentially lower f .

6.5 Unemployment: Appendix

Find related materials here. Some may be repeated from other appendices.

6.5.1 Formulae and Definitions

- **Unemployment Rate:**
 - The percentage of the labour force, those active, able and willing to work, (L) who are actively looking for a job but do not have one.
 - **Formula:** $UR = \frac{U}{L}$
- **Separation Rate:**
 - The flow from employment to unemployment through dismissals, redundancies, firm closures or quits.
 - **Formula:** $s = \text{rate of job separation}$
- **Finding Rate:**
 - The flow from unemployment to employment through matches by firms to workers or workers to firms.
 - **Formula:** $f = \text{rate of job finding}$
- **Natural Rate of Unemployment:**
 - The normal unemployment rate the economy experiences when it is neither in a recession nor a boom
 - **Formula:** $NRU = \frac{s}{s+f}$

7 The Financial System and Macro

We begin the next section with a discussion on the financial system and how the institutions involved within it aid the macro-economy. These institutions help **facilitate the flow of funds**. These flows are conducted:

- **From Savers:** which are households and firms with income they do not need to spend immediately
- **To Borrowers:** firms that need funds to finance investment projects, other households to purchase durables, the government to finance deficits

Following that, we can evaluate the merits of the financial system. Economies with good financial systems will have:

- A higher investment rate, as more funds are available for investors
- Higher efficiency, as agents with low productivity options can transfer their assets to those with high productivity ones
- Increase the amount of borrowing that exists within the economy
- Big ideas are able to meet potential funding

7.1 Components of the Financial System

Below we will dive into more depth on the components of the financial system and list out a few of its components:

- **Financial Markets:** through which households and firms *directly* provide funds to firms and to the government. Examples include:
 - Bond markets
 - Stock markets
- **Financial Intermediaries:** through which households and firms *indirectly* provide funds to firms, other households and governments. Examples include:
 - Banks
 - Insurance Companies

This raises the question: Why do we need intermediaries? Probably the most critical answer to this is due to **Asymmetric Information**. This is when one party to a transaction has more information about this transaction than the other party. Thus, there is a need for:

- **Screening:** to ensure security of good lenders and borrowers. Otherwise those investors whose projects are less likely to succeed are more eager to finance the projects with other people's funds
- **Monitoring:** to ensure the ability to judge performance. Otherwise entrepreneurs investing other people's money are not as careful as if they were investing their own funds

You can think of these two asymmetries as examples of **Moral Hazard** and **Adverse Selection**. Intermediaries help mitigate the effects of asymmetric information. An example illustrating this with banks is given below:

- Screening borrowers for adverse hidden attributes that savers might not detect such as previously bad performance or a bad credit rating
- Restricting how loan proceeds are spent along with monitoring borrowers to prevent issues such as using loans to gamble

This is particularly important for small businesses and households borrowing.

7.2 Balance Sheets

In this section we will explore a bit more of the intricate workings of a bank. Below you can find a tabulated version of the Balance Sheet:

Assets	Liabilities
Loans = \$500	Deposits = \$750
Securities = \$300	Debt = \$200
Reserves = \$200	Capital = \$50

Below is a glossary of the components of the balance sheet:

- **Loans:** the value of loans the bank has made i.e. given out
- **Securities:** the value of the financial assets the bank bought such as stocks/bonds/property
- **Reserves:** this can be cash in the bank's vaults/safes/ATMs or reserves deposited at the central bank
- **Deposits:** the value of current and saving accounts that customers have with the bank
- **Debt:** debts other than deposits e.g. from issuing bonds or from borrowing from the central bank
- **Capital:** the difference between assets and liabilities. **n.b. This capital is different to the equipment and structures discussed in Growth Engines**

The components of the balance sheet seem intuitive enough as to where they come from except **capital**. This can come from two things:

- **Share Issuance:** whereby shares of the bank are sold to investors to gain capital
- **Reinvested retained earnings and asset appreciation:** this comes from reinvested profits from the bank whereby:
 - Kept cash → increased reserves
 - Purchased bonds → increased securities
 - Loans issued → increased loans

Further, asset appreciation can be fed into retained earnings as well.

7.3 Banking Problems

This section will dive into some of the problems that banks may face in a financial crisis

7.3.1 Insolvency

This is the first problem I will discuss. This is when a bank experiences losses in **the value of their assets**. This can come about in several ways but here are two examples:

1. Loan defaults
2. Asset price declines

Thus, when $Assets < Liabilities$ the bank is **insolvent** which means that the bank does not have the asset value to repay the liabilities it owes.

Leverage.

With that in mind, we visit the topic of leverage. This is the use of borrowed money to supplement existing funds for purposes of lending or buying assets. The reason it links to liquidity is because banks can **borrow cheap through deposits i.e. at no cost as interest paid is low** and **lend dearly through bank loans i.e. at high cost as interest received is high**. Generally, the more leverage you accumulate, the greater your profits **if all goes well**. The idea here is that $risk = reward$ hence, if $\uparrow risk$ then $\uparrow reward$.

However two things can happen related to the two examples above:

- Loans \rightarrow they can become non-performing since borrowers cannot repay their interest payments or principal
- Securities \rightarrow fall in value causing fluctuation in the asset side which means that, if sold, they would return less than what was expected, and in the worst cases, less than what they were bought for

So, if you have higher leverage, you're in a riskier position as you need a small fall in asset value to have a large impact on your balance sheet. **Higher leverage means more vulnerability**. We can illustrate with an example below:

Example of Leverage:

Suppose a recession causes our bank's assets to fall by 5% from \$1000 to \$950. This means that $capital = assets - liabilities = 950 - 950 = 0$. Here, we can see that capital is the cushion that keeps you solvent. More capital means you have a bigger cushion. If you were highly leveraged and had no capital, you'd be in the red by \$50.

We can measure this level of vulnerability through the **Leverage Ratio** which is known as $LR = \frac{Assets}{Capital}$ which, for the bank above, is $\frac{1000}{50} = 20$. The higher the Leverage Ratio, the more vulnerable the bank is to insolvency. In the example above, you only need a 5% drop in asset value to become insolvent. If the bank had **borrowed even more**, the percentage drop required would be $< 5\%$ and if they had **borrowed less**, the percentage drop required would be $> 5\%$.

The question that banks and regulators have to ask themselves is what is too aggressive or risky in banking behaviour? What is an acceptable Leverage Ratio for banks to adopt to ensure that they don't hurdle the economy into a financial crisis? This level of how aggressive we should allow a bank to be is debatable and open to question.

7.3.2 Illiquidity

This is the second problem I will discuss. This is when a bank **does not have sufficient reserves to service redemptions**. This is an inability to pay back withdrawals of current and saving accounts which are banks **biggest immediate liability**. Further, this illiquidity can spread to other liabilities the banks may have if they are unable to service their redemptions entirely. This happens because of the characteristics of Deposits and Loans:

- **Deposits are on demand** which is a dangerous aspect of deposits for banks, this means they can be withdrawn at any time with immediate effect. This makes deposits **liquid** which means easy to turn into cash
- **Loans are much slower** which adds to the complication because they are bulk sums that are given out and repaid over a much longer period like 30 years. This makes loans **illiquid** which means hard to turn into cash

Hence, if deposits are demanded but the bank does not have the reserves to service them, they are in trouble because obtaining further reserves from their biggest assets, loans, is very difficult.

n.b. Insolvent does not mean Illiquid. You can be Solvent **and** Illiquid which means you have the asset value to service your redemptions **but not the immediate cash flow to do so**.

Bank Runs Illiquidity can also lead to bank runs. This is when **short-term creditors, including depositors, redeem their funds *en masse***. A run can cause a bank to become illiquid and fail because there is a group mentality that creates a race to see who can get to the bank first to take their money out before the bank has no reserves left to service their redemptions. A run can occur when:

- Short-term creditors doubt the bank's solvency i.e. think their assets are falling in value relative to their liabilities
- When they fear other short-term creditors will run which is related to the group mentality/group think idea

Hence, we revisit the balance sheet:

Assets	Liabilities
Loans = \$500	Deposits = \$750
Securities = \$300	Debt = \$200
Reserves = \$200	Capital = \$50

We can see that if deposits go on a run, the first \$200 will be serviced by **reserves**, then **securities**, which are pretty liquid, can service the next \$500 but the last \$250 deposits might not be serviced due to the rest of the bank's assets locked up in \$500 worth of loans.

This means that the last few depositors, who maybe entered the run a little bit too late, won't be able to get their money out for some time. Hence, the illiquid part comes from the loans not being able to be turned into immediate cash to service the leftover depositors.

7.4 Financial Crises

We begin our discussion of the macroeconomic effects of financial crises here.

7.4.1 Origins

Financial crises often follow periods of **excessive optimism or irrational exuberance**. Here are some examples:

- Financial intermediaries use leverage to make increasingly aggressive loans to firms and households (2007-09)
- Households and financial intermediaries invest heavily in the stock market, often financed by borrowing (1928-30, 1998-2001)
- Households borrow to buy larger and more expensive houses (2007-09)
- Asset Price Booms and Busts are also a feature of the run-up to a financial crisis. This speculation creates a lot of borrowing and spending on margins that create a bubble leading to crazy falls in values of asset prices when people try to cash out

This leads to households, financial intermediaries and other firms becoming **heavily indebted**.

7.4.2 Crisis Triggers

Here are some crisis triggers:

- **Loan Defaults:** some reckless loans prove unpayable by borrowers who are overconfident borrowing from overconfident banks. Mild macroeconomic shocks may also cause loan defaults through an inability to pay as wealth falls or demand falls.
- **Asset Bubble Bursts:** this is when speculators awaken to the unsustainability of a bubble. The expectation of higher and higher prices will come to an end thus they want to exit and they start to sell. This causes other people to sell so to not lose out on returns which causes a **downhill bubble** where prices of securities and assets are pushed down due to high supply but no demand

This leads to **insolvencies at Financial Institutions** where loan defaults and asset price declines lead to losses. Losses, combined with high levels of leverage lead to insolvencies.

Another trigger is related to housing prices and bank insolvencies. **Mortgages**, loans where the house acts as collateral, can default causing one of two things:

1. When house prices are steady, the bank is okay
2. When house prices are falling, the balance-sheet of the bank loses out

When the mortgage defaults, we replace the house loan with the house asset, an illiquid asset, and if the house itself loses value, this could lead to further insolvencies at the bank.

7.4.3 Crisis Catalysts

Having looked at a few triggers, the following will go into drivers which might push the economy into a crisis at a faster pace. **This is an important narrative to remember as to how a financial crisis is caused and catalysed to the point of recession!**

Contagion

This happens when banks affect one another. The narrative begins with an insolvency at some banks. This **directly causes losses to other banks** which may have been lending to them. This reduces confidence in other banks by lenders and depositors. They begin to question:

- How exposed are they to failing institutions?
- How similar were they in their lending practices to failing institutions?

This may cause runs through the withdrawals of deposits and other forms of short term lending. Written below is a part of the narrative of 2008 financial crisis.

Part 1:

In 2008-2009, the collapses of Northern Rock, Bear Stearns, Lehman Brothers and others reduced confidence in other large institutions, many of them interdependent.

Fire Sales

As a result of contagion and insolvency, banks are liquidated such that their assets get sold in an attempt to convert assets into cash to service redemptions. To replace shrinking reserves and **stave off liquidity**, even solvent banks must sell assets. Selling by many banks, **called Fire Sales**, causes steep declines in prices due to excessive supply relative to demand. Part of the 2008 financial crisis narrative is written below:

Part 2:

In 2008-2009, the financial crisis was deepened by the collapse in the price of many securities held by banks. This was evident when looking at the stock market and the price declines recorded.

Credit Crunch

Firms that relied on insolvent banks can no longer borrow due to their closures. Even solvent banks try to turn as much of their loans as possible into reserves thus:

- When loans are repaid, **funds are kept as reserves instead of re-loaned**
- Any cash injection from depositors or lenders are **kept as reserves**

Hence, firms and households find it harder and harder to get funding which means less business development and investment. Part of the 2008 financial crisis narrative is continued below:

Part 3:

In 2008-2009, banks sharply reduced lending to consumers buying homes and to businesses expanding operations and buying inventories.

Recession

All the previous events lead up to a recession. With less credit available, consumer and business spending declines reducing aggregate demand. This means output ultimately falls and employment rises as there is not as much need for workers as a result of a fall in demand. Recalling out equation $Y = C + I + G + (X - M)$, the components of C and I fall drastically along with $(X - M)$ as a result of reduced spending. The 2008 narrative is continued below:

Part 4:

In 2008-2009, unemployment rose above 10% and remained very high for many months after the financial crisis. Real GDP fell as a result across most if not all developed countries.

A Vicious Cycle

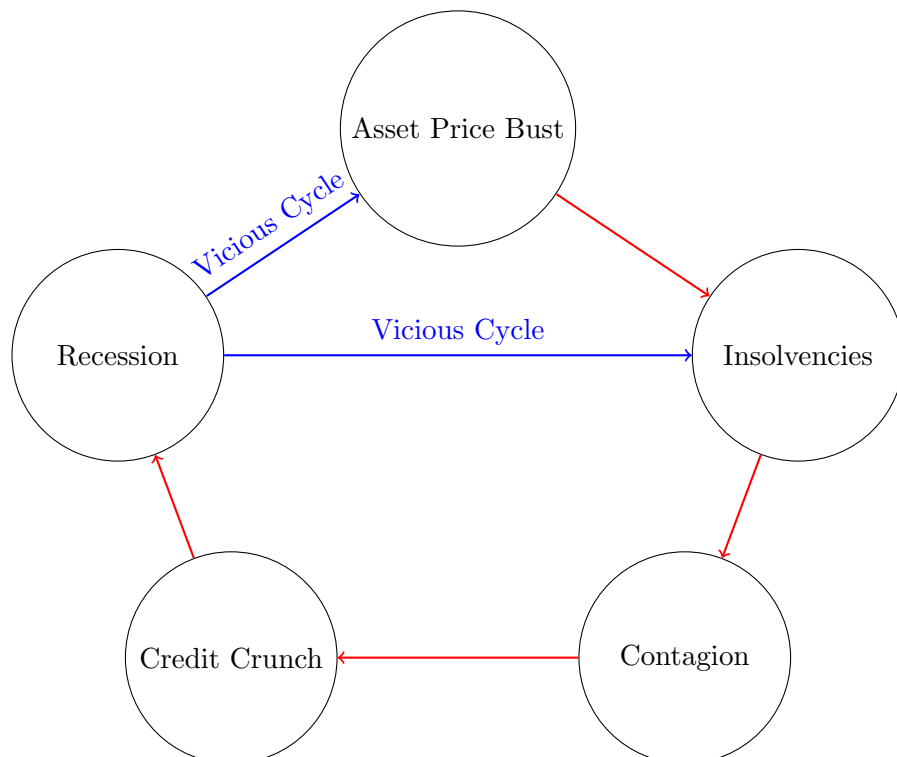

The recession reduces profits, asset values and household incomes increasing defaults, bankruptcies and the amount of stress put on financial institutions. Hence, you can see that **the financial system's problems and the economy's downturn reinforce one another**. This shows how the factors mentioned above **lead into a vicious cycle**. The narrative continues:

Part 4:

In 2008-2009, the vicious cycle was apparent, creating fears the economy would spiral out of control. Spending and GDP continued to decline without a bounce back until much later in the 2010s.

7.4.4 Anatomy of a Financial Crisis

Following the above, find below a graphic that shows the anatomy of the financial crisis.

7.5 Policy Responses

Here, we begin our discussion on the policy responses to a crisis.

7.5.1 Conventional Counter-cyclical Policy

Here are some solutions with conventional policy:

- Loose monetary policy: expand the money supply to lower interest rates
- Expansionary fiscal policy: increase spending and cut taxes

7.5.2 Lending of Last Resort

Here are some resolutions to liquidity crises caused by runs on solvent banks which have insufficient reserves to satisfy withdrawals:

- Central Banks can make a direct loans to solvent but illiquid banks as a **lender of last resort**
- The government can also pitch in with banks and other financial actors (sometimes non-financial)
- Assets are taken as collateral - if you're insolvent, you will not be given a credit line

Note that it is important to remember that **this only occurs to banks which are solvent**. This means that they have the necessary value which is found in their assets to back or repay the loan from the Central Bank over a longer time period. This is because, as discussed with Illiquidity, they cannot immediately convert their assets into redeemable cash.

7.5.3 Nationalisations and Publicly Funded Recaps

These operations are loosely referred to as **Bail-Outs**. There are two approaches to two types of banks:

- **Insolvent Banks:** the government makes up the difference between assets and liabilities, plus some, and becomes sole owner of the bank through **Nationalisation**
- **Near-Insolvent Banks:** the government increases the bank's capital through new share issuance and becomes co-owner of the bank through **Public Funded Recapitalisations**

The key idea in both cases is an injection of capital to let the banks stay afloat. This is basically purchasing shares in the bank and is funded by **taxpayer money** being injected.

7.5.4 Subsidies to Lending

A way to avoid the Credit Crunch aspect of the financial crisis is to provide subsidies to banks to allow them to lend. This gives a bit of liquidity but also, more importantly, **increases the flow of credit** in the economy so business and investment along with consumption don't go into a standstill.

An example could be that for every \$1 that goes out, the government can subsidise it by putting in money that is equivalent to 1 to 2% on the dollar.

7.6 Financial System Reform

Here we begin our discussion on potential paths to reform. Listed below are some of the goals of financial system reform:

- Discourage excessive risk taking
- Make the financial system more resilient to losses
- Reform without impairing the system's function of providing credit

7.6.1 Dealing with the Financial Sector

- Regulation: rules that financial institutions need to follow
- Supervision: Monitoring of financial institutions adherence to rule and risk taking → stopping actions
- Regulators often refers to both those who design regulation and those who supervise it → Central Banks almost everywhere play an important role in regulation and supervision and other institutions help as well such as the **IMF**

There is also a difference between **Micro** and **Macro Prudential Supervision**. Traditionally there was only micro supervision of individual banks but since the crisis, there has been a macro-prudential style of supervision that takes into account the system as a whole.

- Micro: Taking a single bank and analysing it by itself
- Macro: Taking into account how banks affect one another and how the systems regulations have an effect on these interactions

We can analyse a case study with the **Bank of England**. They have three main committees for financial system regulation:

- The Financial Policy Committee (FPC)
- The Monetary Policy Committee (MPC)
- the Prudential Regulation Authority (PRA)

Tools of the FPC

- Countercyclical capital buffers
- Limits of loans-to-value or debt-to-income ratios which reduces the risk and exposure that banks have
- Limits to lending to certain sectors whereby risk is reduced for sectors which are highly leveraged

One of the main ways in which we can reduce exposure and risk is through putting in capital requirements. These are the minimum amount of capital buffers a bank must legally have to operate. Regulatory authorities use ratios to calculate the risk a bank is exposed to:

- **Leverage Ratio:** compares capital to total assets
- **Capital Ratio:** compares capital to risk adjusted assets

From this, the regulatory authority would state that these ratios cannot exceed a certain number otherwise the bank would be deemed to vulnerable to risk and so on. Higher capital requirements reduces the risk of insolvency and hence reduces the risk of potential financial crises. **n.b. Higher Capital Requirements means a Lower mandatory Leverage and/or Capital Ratio**

Bankers, however, would argue against higher capital requirements for the following reasons:

- Capital is expensive and leverage is cheap → the expected return on capital is much higher than the expected return on debt
- Higher capital requirements increase cost of funding → selling shares and also the requirement for a higher return for people to buy these shares presents a barrier
- Less Lending in normal times → this is because of the counter-cyclical capital buffers that regulatory agencies force banks to employ meaning less leverage and less loans put out

7.6.2 Stress Tests

These are annual exercises to evaluate resilience to large adverse shocks. This is usually a test to the balance sheets of a bank following a serious series of events. How they stress test is by creating scenarios that might happen which have a particularly perverse effect on the economy. If they are passed by these banks, it shows a sense of security. If they do not, banks are usually told to increase their capital buffers.

7.6.3 Asset Allocation

Further to stress tests, there may be constraints on the assets that banks can purchase in the first place. This means that there is an emphasis on less risky assets that a bank should be purchasing. This means that bonds or stock bought by banks should not be junk investment graded. In the USA, regulation that prevents deposit taking institutions from trading in risky assets is called the **Volcker Rule** and in the UK it's **Ring-Fencing**.

7.6.4 Compensation Reform

Another way in which the financial system could be reformed is through the way in which compensation is given out:

- **Traditional Structure:** Base salary + Asymmetric bonus based on annual performance i.e. large Π → Large Bonus but with **no negative bonus** for bad performance which means there is an asymmetry as there is a lot of gain but not a lot to lose
- Incentives are not aligned with shareholders or taxpayers → they participate fully on the upside and are sheltered on the downside with their **short term vision**. Bankers take more risk than **desired by shareholders and taxpayers**.
- Asset price bubbles, where performance is high, has long-term loss

Hence to reform, there are some simple guidelines and examples below:

- Less asymmetry in bonus and pay (EU has a limit on bonus sizes)
- Less bonus based on short term performances (Claw-back clauses based on long-term performance)
- Bonus to be kept back and only given if 3Y or 5Y performance is adequate

7.7 Too Big To Fail (TBTF)

When push comes to shove, governments have to bail out large banks in trouble, **this is an implicit bailout guarantee**. This is due to contagion issues that could spread further and wider if a large bank fails due to the amount of dependencies it has.

Effectively, they are safer compared to non-financial or small firms due to this implicit agreement with the government. Cheap bank funding encourages high leverage, risk taking and further growth because the government will bail out the bank at the end of the day.

7.7.1 Dealing with TBTF 1

Have a special regulatory regime for large banks in particular:

- Higher capital requirements
- Specific stress tests with high frequency

7.7.2 Dealing with TBTF 2

Have a different style of bailing out through bailing in, placing the onus on the banks:

- Bail-In rules: public recapitalisation is conditional on losses imposed on bond holders, some debt would be written off during public recap hence no repayment
- Issue: governments defer needed recapitalisation to avoid inflicting losses on bond holders.

7.8 Scope of Financial Regulation

There is a focus on commercial banks:

- Depositors are economically more vulnerable
- Critical for loans to small and medium firms
- Tax payers on the hook through deposit insurance when losses to depositors are limited by the government
- Focus on banks, however, may lead to risky behaviour arising in a non-banking sector

Hence the scope of regulation may need to be widened to ensure that further sectors outside of simply finance do not get too risky in their behaviour. Banks have been accounted for through a lot of regulation but other sectors might need the same treatment.

7.9 Financial System: Appendix

Find related materials here. Some may be repeated from other appendices.

7.9.1 Formulae and Definitions

- **Leverage Ratio:**
 - The ratio of assets to capital in a bank's balance sheet.
 - **Formula:** $LR = \frac{Assets}{Capital}$
- **Capital Ratio:**
 - The ratio of capital to risk adjusted assets.
 - **Formula:** $CR = \frac{Risk\ Adjusted\ Assets}{Capital}$

8 Brexit

This section will cover the Brexit lecture given by **Dimitra Petropoulou**.

8.1 Structure

Below is the structure of the notes.

8.1.1 Where Things Stood

- The June 2016 referendum gave a mandate for the UK to leave the EU
- Article 50 was invoked on the 29th of March 2017
- Scheduled to leave the EU at 11pm on 29th March 2019 (But has failed to do so)
- A no deal exit has been voted against but delays and deals are still waiting on the table to be finalised

8.1.2 What the Notes Address

- What are the main **mechanisms** through which Brexit can impact the UK economy?
- What determines the **direction, magnitude and speed of adjustment** to Brexit?
- How do economists **quantify** the effect of different scenarios on the economy? Why do different reports/studies generate different predictions?

8.2 Impact of Brexit

9 Sovereign Debt Crises

Sovereign Debt Crises are situations in which a government is unable, or is close to unable, to borrow from financial markets. These crises are more common than financial crises, in general. Below I have listed some examples:

- Argentina in 2002
- Greece in 2010 and other Eurozone Countries in 2011-2012
- Venezuela in 2017

9.1 Causes

The main cause is due to heightened financial-market concern that the government might default:

- Unsustainable fiscal path e.g. Greece overspending whilst not taxing enough which leads to large budget deficits in the future
- Large negative fiscal shocks which means a drop in GDP and poor growth prospects e.g. bank recaps in Ireland
- Poor growth prospects which means forecasted GDP is low and forecasted fiscal revenues are also low
- Self-fulfilling debt runs as people don't want to lend as a result of a lack of confidence which means that countries cannot borrow creating a perpetual cycle

9.2 Judging Debt Sustainability

One way of looking at sustainability is through the **Debt to GDP Ratio** which compares how much debt a country has to its total amount of GDP. To test the level of sustainability we can test for:

- Current Level: if its a small amount i.e. 20% of GDP or if it's huge like 150% of GDP
- Direction of Change: if the ratio is increasing or decreasing

Both these factors are important to account for in Sovereign Debt Crises. It becomes problematic when there is a High Ratio that is not coming down or a High Ratio that is continuously going up.

9.3 Currency Denomination

Another factor that contributes to the risk of a Sovereign Debt Crisis is whether or not the debt is denominated in domestic currency or not. Here are the outcomes:

- No default or crisis on debt denominated in a currency that is printed domestically as money can be printed to repay the debt
- There is a risk of default if it is foreign denominated debt e.g. emerging market debt as they cannot print dollars to repay
- There is a risk of default if it is denominated in common currency e.g. in the eurozone as single countries do not have control over the common currency

9.4 Interest Rate Spreads

Government Interest Rate Spreads are defined as: the different in rates paid by two governments. Another indicator of incoming sovereign debt crises can be seen through interest rate spreads. If there are higher interest rates, this is due to a larger risk premium as the government is taking on more risk. These rates spike in the run-up to a crisis and effectively acts as a **Canary in the Coal Mine**.

9.5 Outcomes of SDCs

Listed below are details of certain outcomes of SDCs

9.5.1 Outcome 1: Default

Narrative: when government bonds mature at a certain date, they issue new bonds to pay off the previous bonds. In a crisis, no-one would purchase these bonds which means an inability to pay off the previous bonds.

This results in many years of financial autarky, deep output losses and is the most frequent result of a SDC. Creditors to governments, like banks, could become insolvent which can lead to financial crises.

Further, the country becomes a pariah on International Financial Markets. They are effectively shunned for many years due to their inability to control risk and fiscal responsibility which ultimately paralyses growth, development, consumption and investment.

9.5.2 Outcome 2: Fiscal Adjustment and Survival

To fix the SDC, the government may work towards a balanced budget by introducing large spending cuts and tax increases to service the debt. However, the success of this method out of SDCs is very rare. Here are a few reasons why:

- Deep output losses due to spending cuts and tax increases
- Possible vicious cycles as a result of:
 - Recessions having a negative effect on banks balance sheet
 - Leading to further implicit fiscal liabilities
 - Leading to further losses of investor confidences
 - Leading to a new round of required fiscal adjustment
- **Success is very rare for this method** and when it does come, it comes at a huge cost

If fiscal adjustment improves debt sustainability by lowering the Debt to GDP ratio, it may make sense to do. However, sustainability may worsen if the multiplier is large. The larger the multiplier, the larger the output loss from a reduction of the deficit.

One can also question which one falls faster in this case: the Debt or the GDP? If it is the latter, the country is on track to success, but the former may lead to a precarious situation.

9.5.3 Outcome 3: Bailouts

Bail outs are done through large loans by non-private actors. Examples include:

- The International Monetary Fund e.g. emerging market bailouts
- Other governments e.g. Germany and Greece

The reasons for bailouts are as follows:

- Not bailing out could lead to serious adverse effects on other countries
- Financial losses would have to be picked up by taxpayers
- The idea of contagion means crisis could spread due to interdependence
- Other disruptions may come about such as trade bottlenecking, migration flows being overwhelmed etc.

The Greece bailout example shows success as losses were avoided for core-country banks, contagion was stopped before the crisis could spread to periphery countries and it avoided the risk of the Eurozone breaking up due to the promise of future stability.

Bail outs, as argued with the banks also lead to:

- Creating moral hazard as they have a safety net to fall back on
- Condoning tax evasion, corruption and lack of reform

Hence a solution would be to have bailouts with **tough conditionality**. This means having serious fiscal reform in countries which are in consideration for a bailout.

However, critics also question the balance in bailouts. This is because too much austerity can worsen debt sustainability and if there are large debts in the first place, this might indicate deeper problems that the country must face. Further, the pain inflicted could backfire on the bailout as the country rather defaults than face the harsh conditions under a bailout plan.

Hence, conditions can't be too cruel otherwise the bailout would fail to work before it even begins.

9.6 SDCs and Banking Crises

Declines in the market-value of government bonds weaken bank balance sheets. Weak bank balance sheets increase implicit government liabilities due to the need for recapitalisation or bailing out preemptively. This means that a diabolic loop exists between the two i.e. **SDCs causing Banking Crises and Banking Crises cause SDCs**.
